---

# What is Background?

Background concentrations are generally considered to be the level or amount of a chemical found in common areas not associated with a particular contaminant release.

Parks, roadways, residential areas, non-industrialized properties are typical background areas.

The definition from Tiered Approach to Corrective Action Objectives (TACO (Illinois) is:

“Area Background” means concentrations of regulated substances that are consistently present in the environment in the vicinity of a site that are the result of natural conditions or human activities, and not the result solely of releases at the site.

Information summarized from Urban Area Polycyclic Aromatic Hydrocarbons Study Tiered Approach to Corrective Action Objectives, Illinois EPA

MPA – Global Solutions  
[www.mpaglobalsolutions.com](http://www.mpaglobalsolutions.com)

---

# Motivating Factors for the Study

ALARA Principle – Remediation to target levels < background is not practicable, cost efficient, or beneficial from a health protection standpoint;

Delineating limits of contamination from point sources;

Screening out sites from Preliminary Investigations relative to more detailed studies;

Understanding local conditions – will be highly variable

Because we can – large amounts of data are available, and can be retrospectively analysed, as long as amenable to electronic data reading and manipulation (AGS data format proved to be the key)

MPA – Global Solutions

---

# Study Objectives

Assess anthropogenic background levels of PAH levels detected in East Anglia Soils.

- Rural (no identified current or historic source)
- Urban (no identified current or historic source)
- Industrial
- Farms
- Automotive works

---

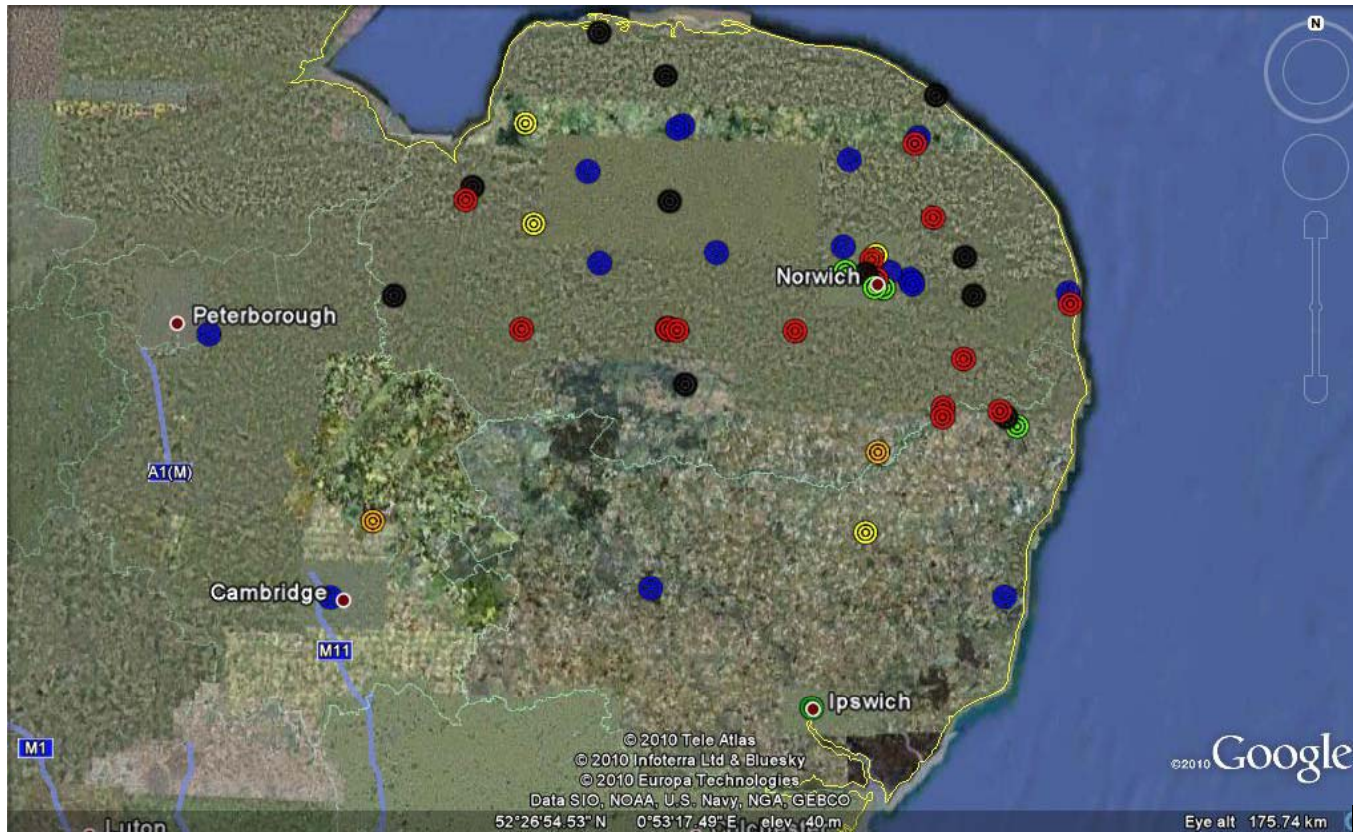

# Design

## Retrospective examination of SI data between 2004 and 2010

- Non-structured selection of sites – SIs conducted by Harrison Group with archived AGS electronic data
- Classification of sites as per land uses based on Desk Study information
- Statistical review of PAH data
  - Distributional characteristics
  - Outlier identification
  - Development of baseline data set
  - Derivation of statistical parameters
  - Comparison with published values

# Design

| Group        | Sites     | Samples    |        |
|--------------|-----------|------------|--------|
| Farm         | 2         | 13         | Yellow |
| Industrial   | 15        | 104        | Red    |
| Urban        | 7         | 28         | Green  |
| General      | 16        | 69         | Blue   |
| Automotive   | 10        | 45         | Black  |
| <b>Total</b> | <b>50</b> | <b>259</b> |        |

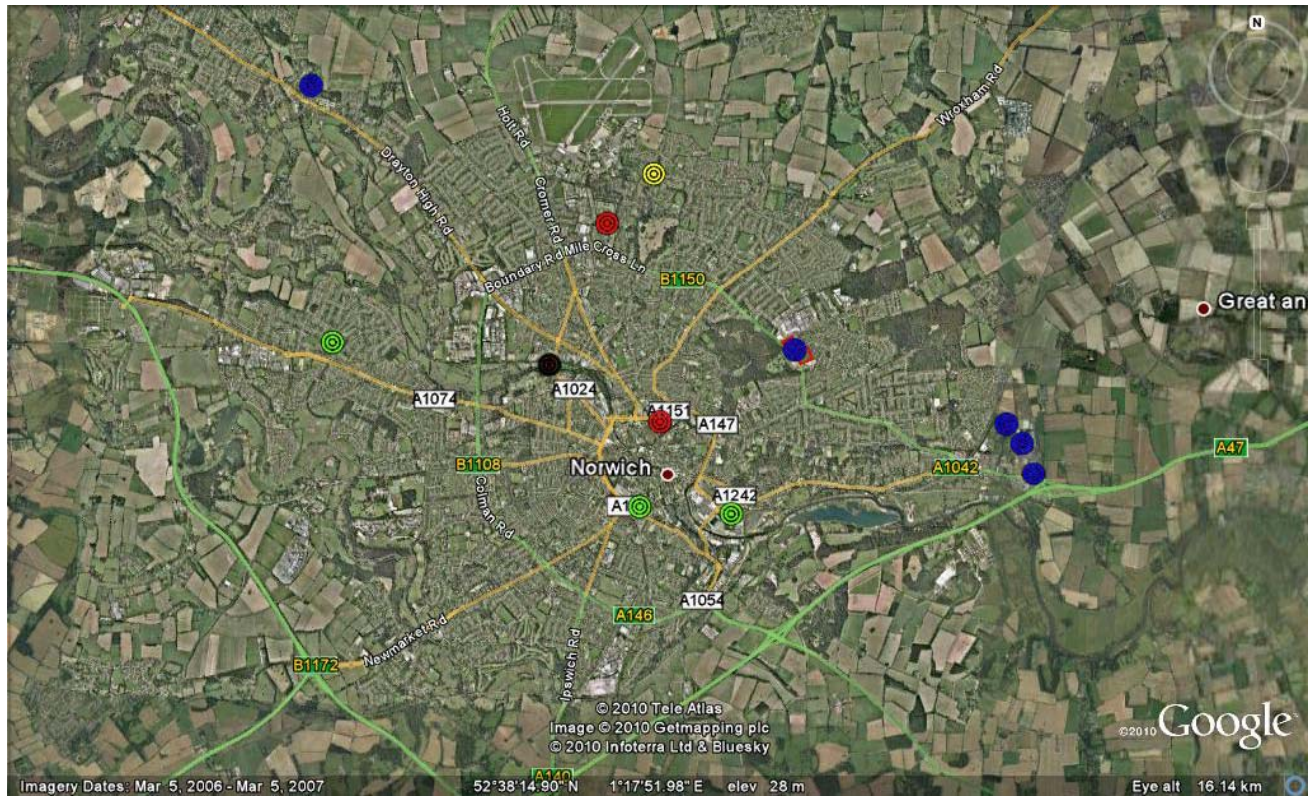

MPA – Global Solutions

### Statistical analysis :

- Normal probability plots
- Tests for normality (Shapiro Wilkes)
- Test for outliers (Grubbs Test)
- Upper Confidence Limits (Normal, Log-Normal, Non-Parametric)
- 95% Upper Tolerance Limits
- Multi-Variate Analysis (Fingerprinting)

### Spatial Analysis

- Lateral and Vertical extent
- Hot-spots
- Concentration Gradients

# Summary Statistics - General (no identified current or historic source)

Summary Statistics General Data

| Constituent                | Min | Max   | Mean | Geometric Mean | Log-Normal |                 |                           |

# Statistical Distribution - General (no identified current or historic source)

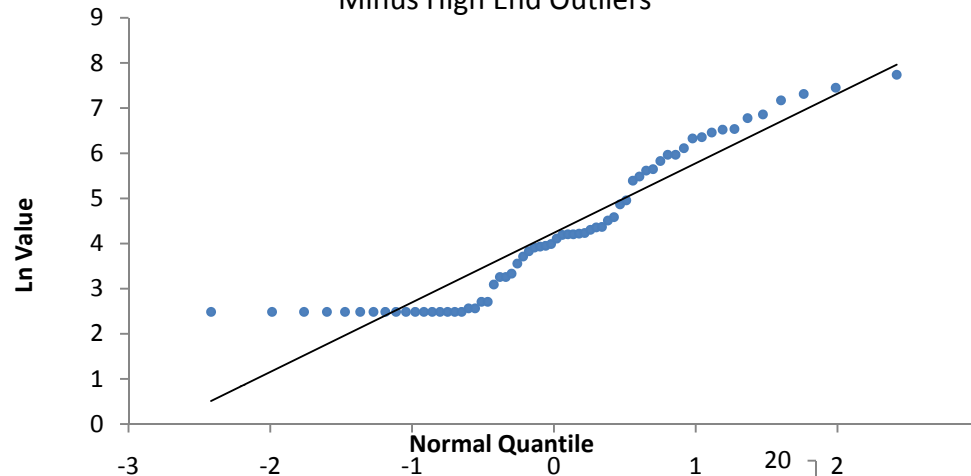

- High end outliers
- Left censored (detection limits)
- Bi-modal

# Statistical Distribution - General (no identified current or historic source)

Normal Probability Plot BaP - General Land Use  
Minus High End Outliers

- Closer conformity with Log-normal Distribution
- Left censored (detection limits)

BaP in General Soils

# Dealing with Non-Detects

---

- Detection Limit (approach used)
  - Detection Frequency 75%
- $\frac{1}{2}$  Detection Limit
- Maximum Likelihood Estimation for Left Censored Data - replacement of non-detect values with fitted values
  - To be assessed

# Pattern Assessment – Variation in Isomer ratios (assessment of discrete sources)

- Principal Components Analysis of Isomer Ratios
- Data divided by concentration – assess if outliers are from unique sources

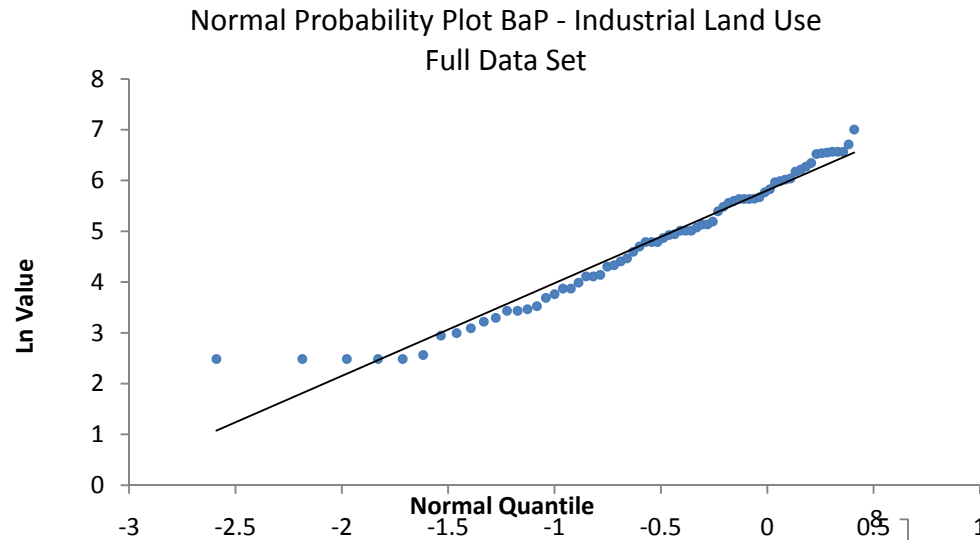

No clear difference by Concentration level.

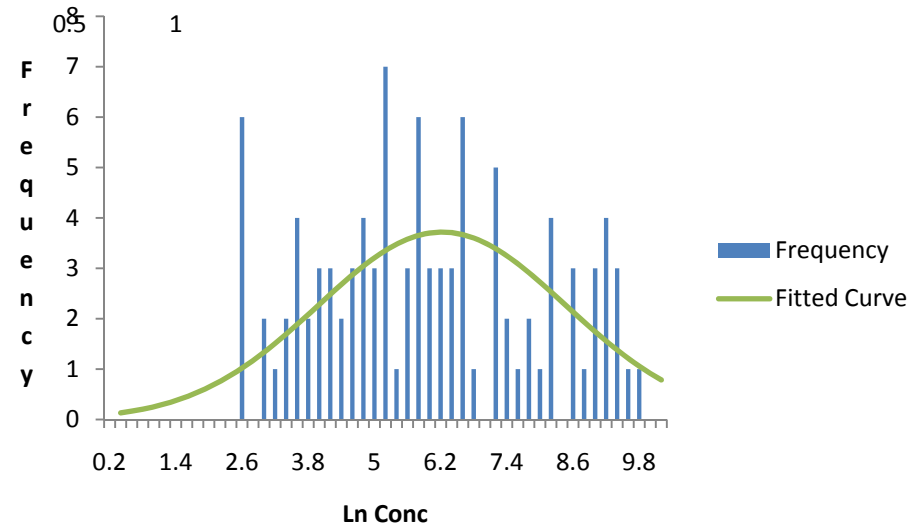

Most samples showed very similar profiles

Suggestive of common source

# Statistical Distribution - Industrial

- Good fit with Log-normal Distribution
- Left censored (detection limits)

# Data Comparison Across Groups

| Constituent | Min | Max    | Mean | Geometric Mean | Log-Normal |                 |                           |
|-------------|-----|--------|------|----------------|------------|-----------------|---------------------------|
|             |     |        |      |                | 95% UCL    | 95th Percentile | 95% Upper Tolerance Limit |

## Comparison with Published Literature

---

### **Background Levels of Polycyclic Aromatic Hydrocarbons (PAH) and Selected Metals in New England Urban Soils**

L. J. N. Bradley B. H. Magee and S. L. Allen Journal of Soil Contamination, 3(4): (1994)

- Samples of surficial soils from urban locations in three New England cities. Sixty samples – twenty from each city

### **Concentrations of Polynuclear Aromatic Hydrocarbons and Inorganic Constituents in Ambient Surface Soils – Chicago Illinois, 2001-2002**

Kay et al, 2003, USGS Report 03-1045

- 57 Sites in Chicago Metropolitan Area. One sample from each site

### **PAHs in background soils from Western Europe: Influence of atmospheric deposition and soil organic matter**

Jae Jak Nam et al. Chemosphere 70 (2008) 1596–1602

- 53 Soil Samples from Norway and UK

MPA – Global Solutions  
[www.mpaglobalsolutions.com](http://www.mpaglobalsolutions.com)

## Comparison with Published Literature

---

Broadly, our results are similar to the observations made elsewhere:

**UK soils** – Geometric Mean BaP 46 ug/kg – range 1.8 – 1600; (our data Geo. Mean 52 range 6-1724, after high end outliers were excluded)

**Chicago soils** – BaP 95 Percentile 2,100 ug/kg; (our data 2,500 including outliers, 1,700 excluding)

Highly spatially variable – orders of magnitude differences within 300 metres of each other.

**New England Study** – BaP range 40 – 13,000 ug/kg, and 95 percentile 1,800 ((our data 2,500 including outliers, 1,700 excluding)

# Conclusions – Points for Discussion

---

Stationary and mobile anthropogenic sources account for the majority of PAHs, with great variability regionally and locally.

Remediation should not commence without establishing / assessing a site-specific background, if possible.

The impracticality and infeasibility of remediation to guideline levels if naturally occurring background exceeds the maximum allowable value is self evident. It deems remediation unnecessary and unproductive in such scenarios.

MPA – Global Solutions  
[www.mpaglobalsolutions.com](http://www.mpaglobalsolutions.com)

---

ALARA principal is a vital consideration (setting cleanup levels as low as reasonably achievable). Assessment and consideration of background would be imperative.

A tier-based guideline system may be very beneficial, where the central tendency and maximum values are compared with relevant background numbers (95% UCL), (95<sup>th</sup> percentile). This is particularly relevant in the current times, given the broader issues of greenhouse gas emissions, and need for efficient utilisation of economic resources.
